

## **APP NOTE: AUTOMATIC GENERATOR STARTING**

### **SAFETY WARNING:**

A generator is often viewed as a necessary back up source of electricity for renewable energy systems. Many see generators as a necessary evil. Without taking sides in that discussion, we do warn that providing automatic starting of a generator can be dangerous. There are those who believe that a generator is hazardous enough just when running since the combination of fuel, heat, sparks and exhaust fumes are not friendly to life. So to have a set of preprogrammed electronic parameters that start the generator without requiring a person to be present to make sure it is running safely, is a fire waiting to happen. So, use caution if you need to install automatic generator starting at your home. And please make sure your customer understands the risks if you are asked to install one for someone else. It will probably be at a remote location which brings some interesting responsibilities with it.

### **APOLLO SOLAR IS NOT IN THE GENERATOR BUSINESS:**

Apollo Solar is NOT in the generator business. Apollo Solar does not recommend nor discourage any specific brand or type of generator. It follows that we can not provide tech support for generators. Our Charge Controllers and Inverters work with generators, but our expertise and support begins and ends with our products.

### **NOT ALL GENERATORS CAN BE STARTED AUTOMATICALLY:**

The smallest size generators (about 2kW or less) don't have a starter motor. They require that a person pulls a cord. Obviously we can not discuss remote starting of that class of generators. Moving up to the 5kW or 6kW, they include starter motors and a small battery. (The battery presents its own set of problems.) But some of them have manual chokes which require a person to monitor the engine after he pushes the start button. Those generators are not good candidates for automatic starting either. When you get up to the 8kW to 10kW generators, there is enough money in the genset that wiring is usually provided by the generator manufacturer for a start switch which has the ability for remote starting and stopping. If these serious machines are of good quality, they have enough smarts so that a simple remote ON and OFF switch will allow it to be started and stopped. Importantly, these gensets also monitor a few critical parameters like oil pressure and some temperatures so they can turn themselves off before self-destructing.

### **SMALL SYSTEMS WITH PULL START GENSETS:**

For small (<3kW) systems, if the PV is not sufficient to keep the batteries charged, then the choice is simple: Periodically pull out a small generator, hook it up to the AC Input of the Inverter/Charger and pull the cord to start it. Keep an eye on it and turn it off when the batteries go from Bulk into Absorb. They will then be about 90% full.

### **LARGE SYSTEMS WITH SMART GENSETS:**

From both the business and system design perspectives, we believe that if an installation requires a large (>10kW) automatic starting genset, it should be a self contained module which takes care of all its own issues internally. In other words, the external system should

tell the generator when to turn on and when to turn off, but it is up to the generator to do everything it has to do so it doesn't burden the renewable energy system.

**OUR T80 CHARGE CONTROLLER PROVIDES A GREAT SOLUTION:**

If there is a T80 or T80HV in the system, it provides the means to start a genset based on the battery State of Charge. The terminals on the generator itself are where the AUX Relay in a T80 gets connected. The logic is that if the battery State of Charge goes down to 50% for example, the AUX Relay contacts in the T80 close to start the generator. When the State of Charge is above 80% for example, the AUX Relay contacts open thus stopping the generator.

That plan uses the [expensive] fuel only when there is not enough free solar energy to keep the battery charged, and it stops using fuel when the bulk charge is completed. This allows the solar energy to complete the long Absorb charge stage bringing the battery up to 100% full.

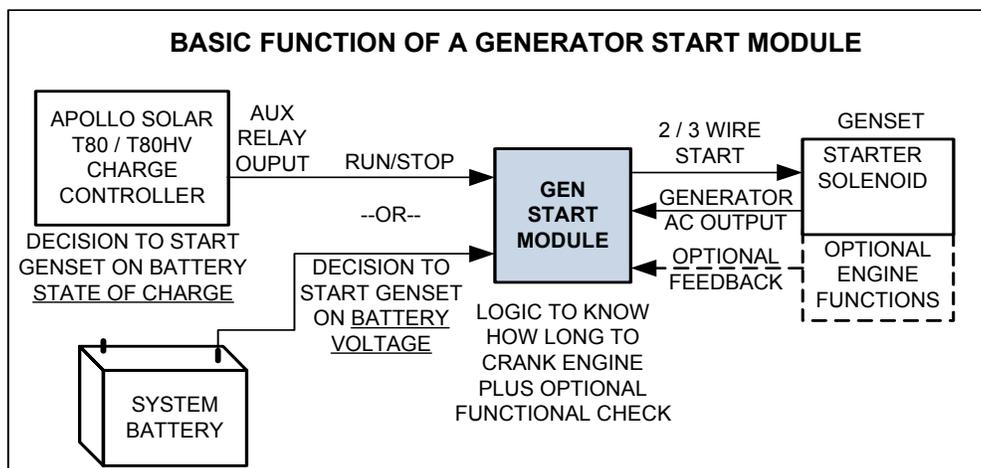

**SETTING THE GENERATOR START POINT:**

Of course every site is different with regard to the amount of sun, the size of the PV array, the cost of fuel, the degree that the battery power is critical, and many other points. Apollo Solar is not in a position to make any recommendations as to the exact State of Charge settings. Those settings must be established and supported by the installer / integrator of the system.

The Apollo Gateway provides important feedback to help the installer fine tune these settings. By studying the results via the internet, a person with expertise in this area can adjust the settings for the optimum use of fuel while making sure that the batteries are not damaged by deep discharging.

**THE CHALLENGE – GENSETS BETWEEN 3kW AND 10kW:**

The middle ground (between 3kW and 10kW) can be a problem. There may not be enough money in a mid-sized genset for the manufacturer to make it as smart as you need it to be. You will then have to include a Generator Starting Module which adds the smarts to know how to deal with the glow-plug on a diesel, how long to crank the starter, how many times to crank it before it is flooded, how long to wait between cranking, etc, etc. There are companies who make these modules for \$300 to \$600. Interfacing them correctly to any specific generator can be complicated and time consuming. We believe that the tech support department at the generator manufacturer of choice should help the installer solve those problems.

In the block diagram above, the Gen Start Module is the device that must be added to make the genset as smart as it has to be for automatic starting. The decision of when to start is still made by the Apollo Solar T80 or TSW True Sine Wave Inverter / Charger. The third party Gen Start Module is connected between the T80 AUX Relay contacts and the generator.

Atkinson Electronics makes 2 such modules which are popular in the industry. The more sophisticated unit will turn on the glow plugs on a diesel generator. Atkinson is a good place to call for technical support on their modules and generators themselves.
